

# Bazaar – php example code – part 17 – ordering tables by category

Article focus on way how to display content of list inserted in table order by activating visual elements in header of appropriate table. Our focus is enable reorder listening ascending or descending way along selected column.

## Expectations from ordering system

Content of the lists display usefull information for page users. Quick way how to obtain relevant data is ordering them ascending or descending by interesting category. For implementation of ordering ability in our tables we must:

- add links (best way is to associate them with nice graphics that is intuitive for the user) for ascending or descending ordering in header of our table
- generate GET links for submitting necessary data for ordering functionality
- prepare appropriate scripts handling calculations for number of displayed data, use LIMIT functionality in SQL queries
- generate pagination links at the left bottom part of our lists for browsing functionality through our results

How ordering works, brief introduction – our code must take in mind number of items for display and number of list items for

display. After calculations number of browsable page, function for generating pagination links must generate appropriate links. User select appropriate page or next/ previous page. Data from user are send to themself as GET links. From obtained data our code prepare SQL request containing LIMIT keyword for selecting only rows from appropriate calculated position and with expected number of selected items. In table output is next displayed selected data and links on page must be displayed with respect of actually selected page and ordering.

Next pictures visually display our expectations/ implementations of this functionality.

Name	Price	Category	Screenshot	More info
E-shop pre analysis	89 €	web/e_shop		
E-shop for beginners	150 €	web/e_shop		
Analyse for e-commerce	350 €	web/e_shop		

Links for ordering output data along selected category

Pagination on the bottom of the page

## Code implementing pagination on page

First discussed code is responsible for generation of links at the bottom part of a page.

Our code page named functions.php contains function invoked in other pages handling pagination functionality. Content of this function is:

```
<?php
/**
 * Changelog
 * v 1.0 - first working version, update 6.11.2020
 * v 1.1 - for ordering option was updated header of function
 * by adding $sort -> $sort_by and new $order
 *           $order variable can be 1 for ASC order and -1
 * for DESC order, update 28.11.2020
 */
function generate_page_links($user_search, $sort_by, $order, $cur_page, $num_pages) { //($user_search, $sort_by, $order, $cur_page, $num_pages);
```

```

$page_links = "";
echo "<br>";

// if this is not first in row, we need generate the „previous“ link
if ($cur_page > 1) {
    $page_links .= ,<a id="pagination" href=" . $_SERVER[PHP_SELF] . ,?usersearch='
        .$user_search . ,&sort_by=' . $sort_by . ,&order=' . $order . '&page=' . ($cur_page - 1) . ,"></a>';
}
} else {
    $page_links .= ,<span id="pagination"></span> ,;
}
}

// Loop through the pages generating the page numbered links
for($i = 1; $i <= $num_pages; $i++) {
    if ($cur_page == $i) {
        $page_links .= ,<span id="pagination">' . $i. ,</span>';
    } // span inline element mark non a tag (unlinked number) as pagination for further formating by css
    } else {
        $page_links .= ,<a id="pagination" href=" . $_SERVER[PHP_SELF] . ,?usersearch='
            .$user_search . ,&sort_by=' . $sort_by . ,&order=' . $order . '&page=' . $i . ,">' . $i . ,</a>';
    }
}

// If this page is not last in row, generate „next“ link
if ($cur_page < $num_pages) {
    $page_links .= ,<a id="pagination" href=" . $_SERVER[PHP_SELF] . ,?usersearch='
        .$user_search . ,&sort_by=' . $sort_by . ,&order=' . $order . '&page=' . ($cur_page + 1) . ,"></a>';
}
} else {
    $page_links .= , <span id="pagination"></span>;
}

```

```

pan>';
}

    return $page_links;
}
?>

```

In our code are at current time not implemented all expected functionality. User search is not passed but all other arguments are used for passing necessary data for generation of pagination links.

Our code must handle situations when there are no more page next or previous, and must be able to generate all other numbered page links. All links are selectable on focus by user.

## Real implementation on pages

Next part of index page is responsible for ordering data and iterating through all available pages with content. Our code relevant for this functions is highlighted by blue color.

```

$image_location = IMAGE_PATH.$row[,screenshot1'];

echo „<td id=\“gray_under_picture\“> <img src=\“$image_location\“ alt=\“ screenshot of product primary \“ height=\“250\“> </td>“;
echo ,<td colspan=\“1\“><a id=\“DEL“ href=\“item.php?item_id=\“. $row[,item_id’]. ,“><img id=\“next“ src=\“./images/next.png\“> </a></td></tr>‘; //construction of GETable link
echo „</tr>“;
echo “ </div> “ ;
}

echo „</table>“;
//count nuber of pages total
$num_pages = ceil($total / $results_per_page);

```

```

        //generate navigational page links if we have more than one page

        if($num_pages > 1) {
            $user_search = „“; // not implemented yet, then set as clear values
            if(empty($sort_by)) { // if not obtained by get then default order is applied
                $sort_by=“default”;
            };
            if(empty($order)) { // if not obtained by get then default order is applied
                $order=“1”;
            };

            // included function for pagination generation function stored in functions.php page
            echo generate_page_links($user_search, $sort_by, $order, $cur_page, $num_pages);
            echo „<br><br>“;
        }
        // Free result set
        mysqli_free_result($output);
    } else{
        echo „There is no item for sell. Please add one.“; // if no records in table
    }
} else{
    echo „ERROR: Could not able to execute $sql. “ . mysqli_error($dbc); // if database query problem
}
// Close connection
mysqli_close($dbc);

```

From our code excerpt can be visible these parts: 1) parts responsible for calculating number of necessary pages for display, 2) part handling ordering logic responsible for creation of SQL queries, 3) table part responsible for display

of data and generating links and part 4) invoking function for generating pagination information at the bottom part of page.

## Conclusion

Our code fulfil our expectation. Because we used functional approach, maintainability is hard. One big problem that we gained is visible if we work with two or more pagination/ordering functionality. information about current page is passed by GET link and is one for all ordered tables. When we order along one table, also other tables are iterated by the same page. But this is acceptable solution. because focus of user is only for actually handled part of page.

For futher improvement is way how to maintaing ordering along two or more pagination links best part of focus. Also further abstraction this functionality with OOP implementation can lead to a more reusable part of code.

Full code for further study can be obtained from [github](#) here.
